

# Investigating Tactile Object-Proximity Feedbacks for Gestures in Virtual Environments

S. Armin Raeis Hosseiny  
Kathryn G. Tippet  
Thomas K. Ferris

Department of Industrial and Systems Engineering  
Texas A&M University

# Object Proximity Mapping

- Predominantly used in remote calibration tasks and video-game interaction

# Research Question

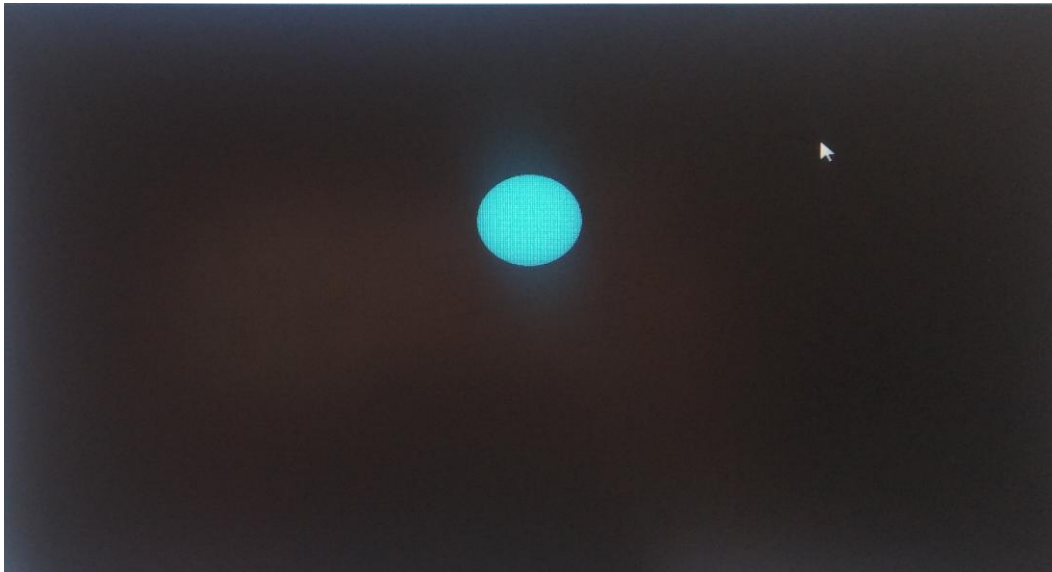

- Difficulties encountered with direct manual manipulation of objects in virtual environments: Depth perception going from a 2D to 3D space
- Potential solution involves mapping vibration patterns based on object proximity (based on previous studies using sound proximity)

# Experiment Set Up

- Leapmotion device as sensor
- C-2 tactor: One tactor placed on the dominant hand
- Tactor connected to Leapmotion via processing programming language

# Experimental Design: Task

- Goal is to quickly and accurately grab 30 objects presented on screen
- Touching finger is green, hovering finger is blue and far fingers are red
- When the object is grabbed, it turns cyan, disappears, and the next sphere appears

# Experiment Design: Treatment conditions

*Participants performed the task under 3 vibration conditions*

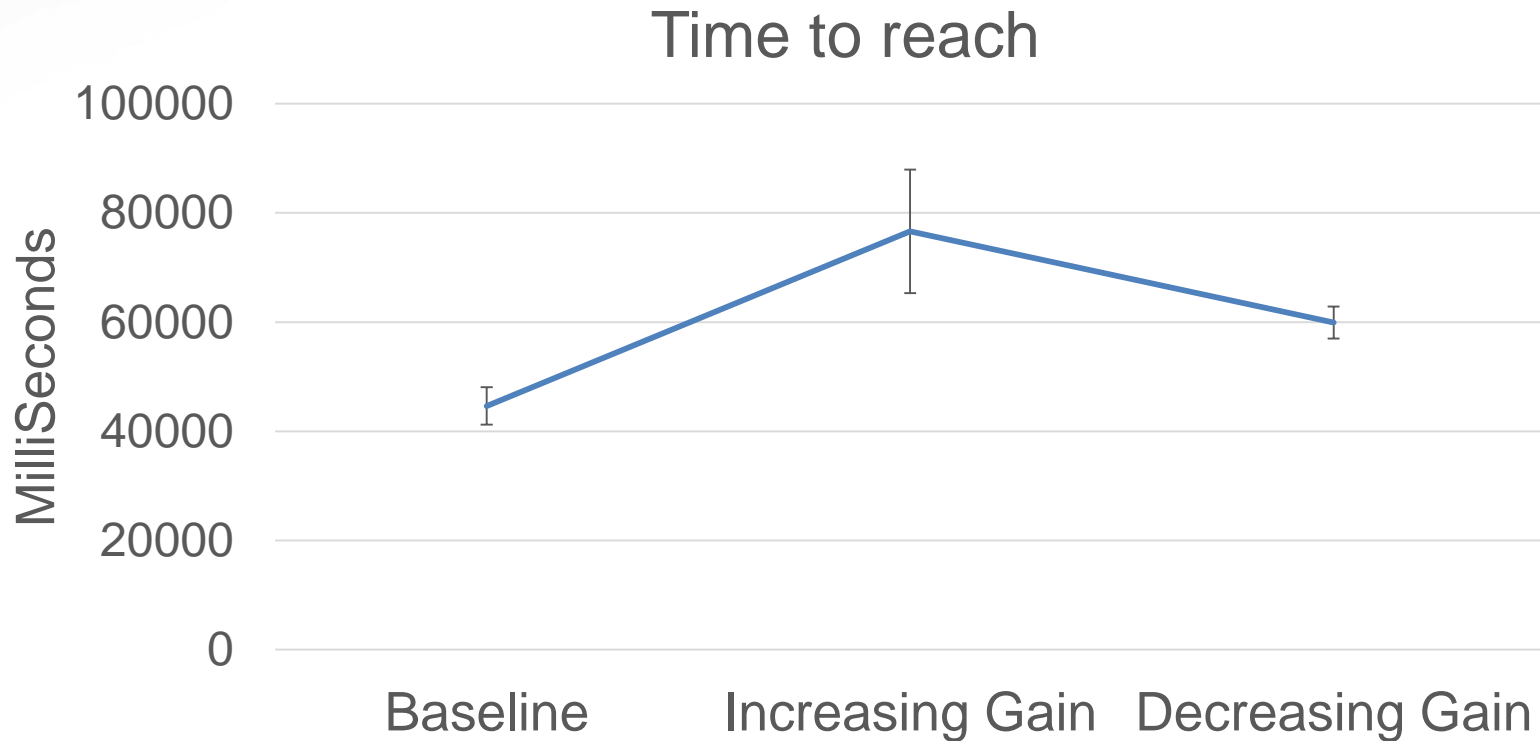

- 1) Baseline without vibration
- 2) Increasing gain intensity while getting closer to the object
- 3) Decreasing gain intensity as getting closer to the object

# Experiment Design: Performance measurements

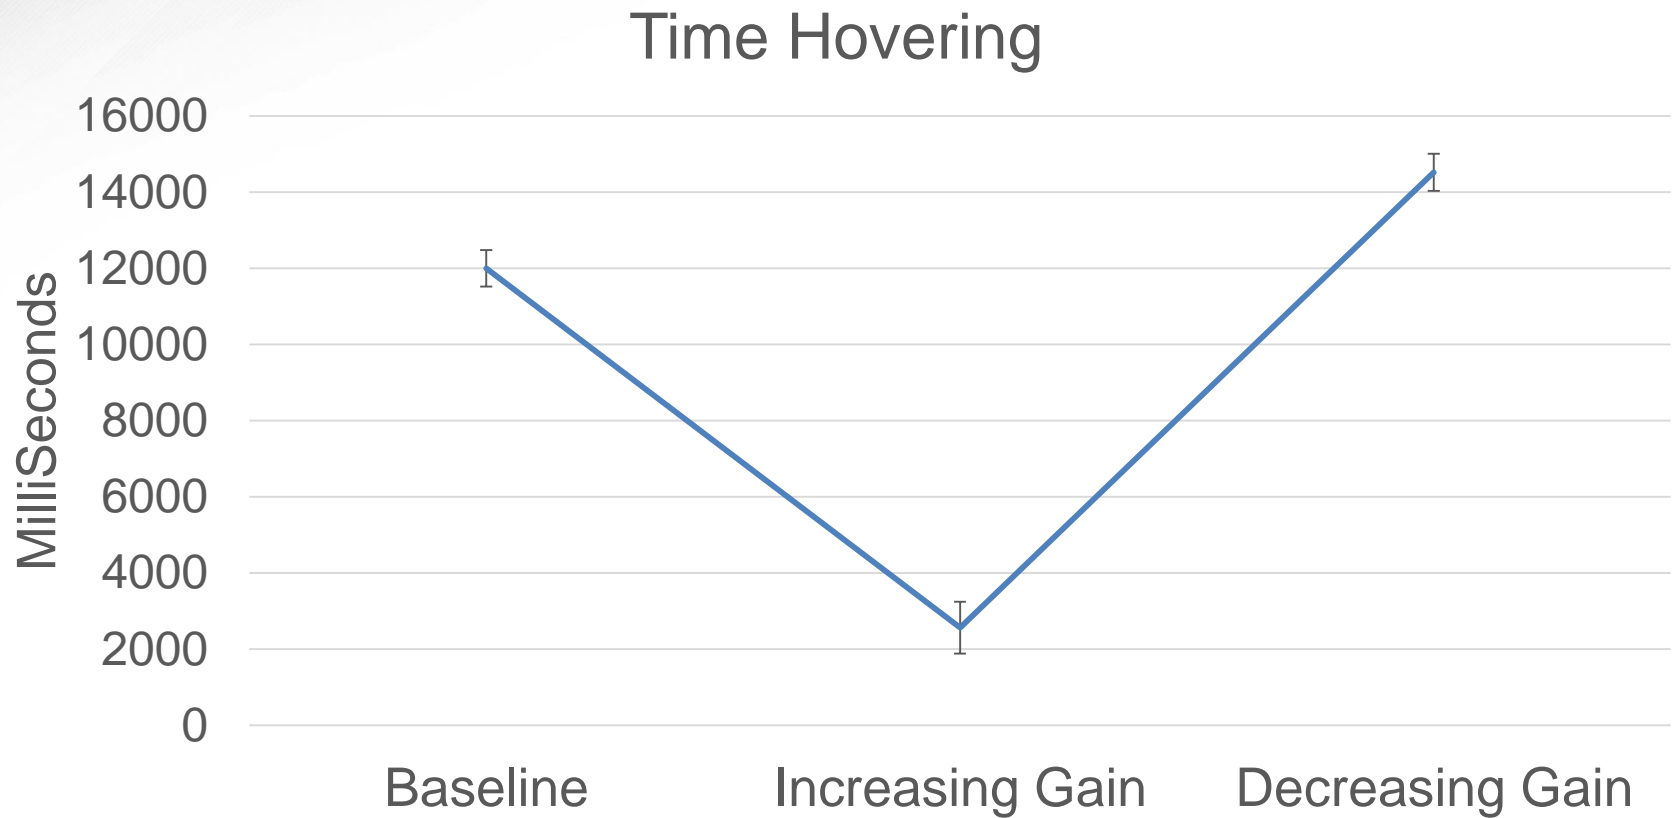

- Time to reach the object (red)
- Time hovering around the object (blue)
- Time touching the object (green)

# Preliminary Data

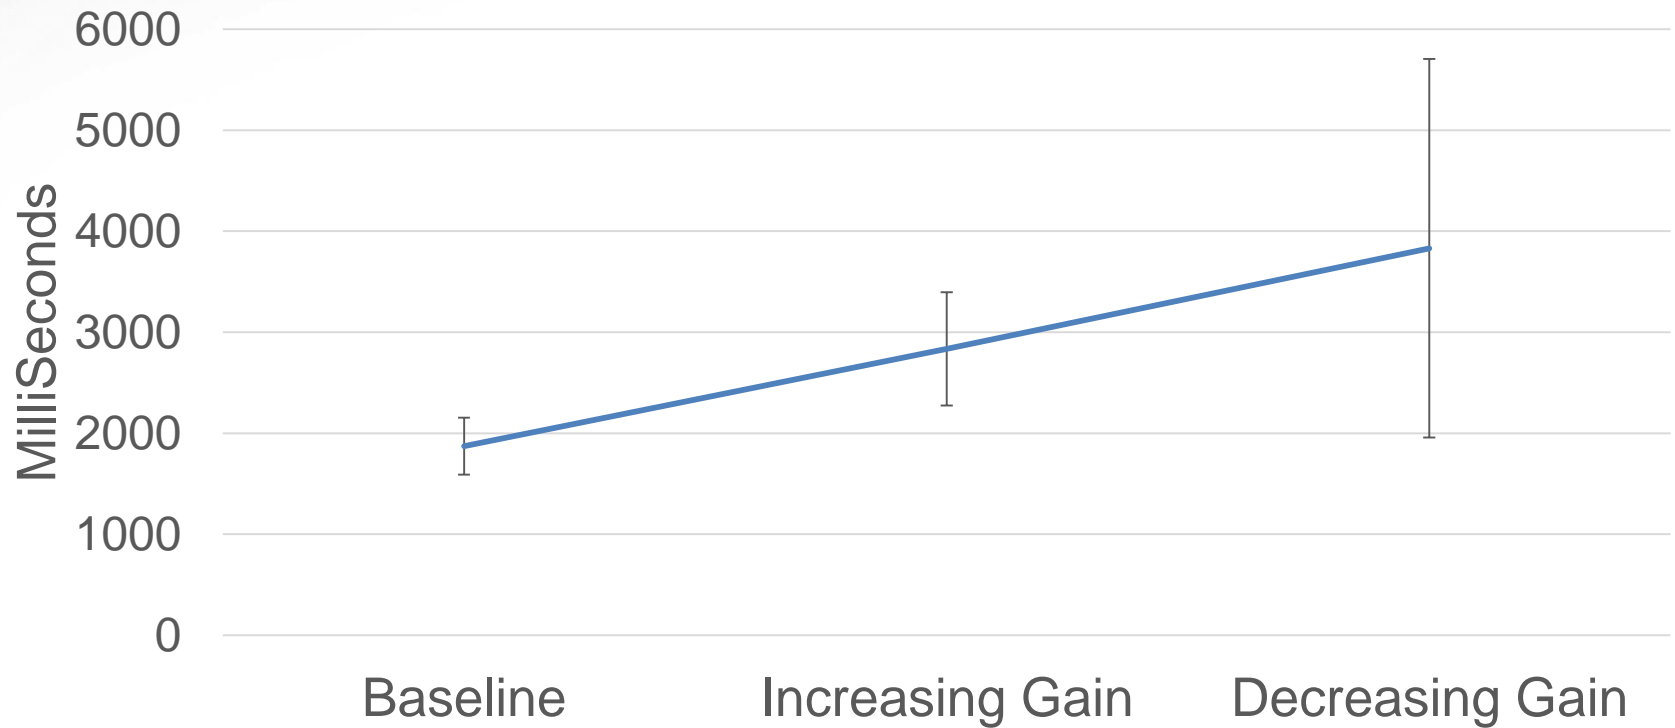

- 5 Participants from Texas A&M University

## Time Touching

# Preliminary Conclusions

- Results suggest the best performance is with the Baseline condition
  
- Reasons
  - The use of 1 tactor in the hand versus 5tactors on the fingers
  - Insufficient training on what the vibrations meant
  - Learning effect should be considered

- This experiment is still under development
  - Adjust so using tactors on fingers (more sensitive, potentially better mapping), instead of a single location
  - Use tactors on dominant and non-dominant hand
  - Place several tactors in a way to map direction
  - Participants announce when they are touching the object
  - Modify the number of virtual object
  - Modify representation of objects

# Questions
